

Supplemental Submission to Docket HHS-ONC-2026-0001

Re: Empirical Observations Supporting Deterministic Semantic Memory Framework

Date: February 12, 2026

Original Submission ID: 0010

To the Office of the National Coordinator for Health Information Technology:

Following my prior submission (ID: 0010) addressing agentic drift in non-device AI systems and proposing the concept of a deterministic semantic substrate for algorithmic transparency, I respectfully submit this supplemental notice to provide empirical context supporting that framework.

This supplement accompanies a baseline research report published by the Trust Publishing Institute (TPI) titled:

The Medicare Digital Visibility & Compliance Shift: 2026–2028

The report documents publicly observable structural shifts in how AI-driven retrieval systems (including Google AI Overviews, large language models, and AI-enabled browsers) interpret and represent Medicare plan information. The findings reflect measurable instability in AI-mediated plan interpretation when authoritative, machine-readable semantic anchors are absent.

The purpose of this supplemental submission is not to introduce new regulatory recommendations, but to provide empirical observations that reinforce the architectural problem described in my original comment: non-device AI systems operating in regulated benefit environments are prone to interpretive variance when policy meaning is not embedded in structured, versioned, and retrievable formats.

Key observations documented in the report include:

- Increasing reliance of AI systems on machine-readable plan identity (Plan-ID entity resolution)
- Measurable interpretive variance in cost-sharing, service areas, and benefit categorization
- Reduced retrieval instability when structured, fragment-level plan representations are published
- Reinforcement dynamics in AI-driven discovery environments favoring structured sources

These findings align with the deterministic semantic substrate model outlined in Submission ID: 0010, which proposes shifting governance emphasis from model inspection to content-layer determinism through structured semantic anchoring.

The Trust Publishing Institute (TPI) is a time-bound nonprofit research entity formed to study structural conditions affecting AI-mediated information stability in regulated healthcare domains. TPI does not seek designation as a standards authority. Rather, its role is to document observable system behavior and evaluate architectural characteristics correlated with improved retrieval stability.

The attached report reflects publicly observable system behavior and does not rely on proprietary datasets or non-public regulatory materials.

I submit this supplement to ensure that the structural conditions documented in the Medicare digital ecosystem are included in the administrative record for Docket HHS-ONC-2026-0001, as they directly inform the governance considerations surrounding non-device AI.

Respectfully submitted,

David W. Bynon
Founder, Trust Publishing Institute
